

Thermometers

(December 2023)

1. Organoanthropogenic warming theories contend that the warming induced by fossil fuel burning is 1.6 C per century, or 0.016 C per year;
2. Surely such slight annual increase can hardly be measured globally with any semblance of scientific accuracy;
3. However, the media and governments alike seem to argue with great indignation that the warming in 2023 was considerable and never experienced in the past five billion years of Earth's history;
4. Surely they can't think of a warming as minute as 0.016 C;
5. Therefore, if warming there was, it must have been much greater than 0.016 C;
6. Ergo either:
 - a. someone can't read a thermometer, or
 - b. someone's wrong with the theory¹.

¹ Note: the validity of any scientific theory is instantaneously invalidated whenever experimental readings depart from theoretical predictions, one way or the other.
